

# NUMBER REPRESENTATION

# Why we study number representation

- To meet design metrics minimum number of bits that result in correct answer are required
- Additional bits will results in:
  - Additional Hardware
  - Increases power (Because of more switching of gates and wires)
  - May increase latency

# Fixed point integer

- Unsigned (Non-negative integer)
  - For n-bit number, range is given by
$$[0, 2^n - 1]$$
  - Ex.  $111$   
range  $[0, 7]$

# Fixed point integer

- Signed

- Sign magnitude

- For n-bit number, range is given by:

$$[-(2^{n-1} - 1), 2^{n-1} - 1]$$

- Ex.
- |  |          |           |   |   |  |          |           |   |    |
|--|----------|-----------|---|---|--|----------|-----------|---|----|
|  | 0        | 111       | → | 7 |  | 1        | 111       | → | -7 |
|  | ↓        | ↓         |   |   |  | ↓        | ↓         |   |    |
|  | Sign bit | Magnitude |   |   |  | Sign bit | Magnitude |   |    |

- Signed 2's complement

- For n-bit number, range is given by:

$$[-2^{n-1}, 2^{n-1} - 1]$$

- Ex.
- |  |    |   |   |   |   |  |  |    |
|--|----|---|---|---|---|--|--|----|
|  | 1  | 1 | 1 | 1 |   |  |  |    |
|  | ↓  | ↓ | ↓ | ↓ |   |  |  |    |
|  | -8 | 4 | 2 | 1 | → |  |  | -1 |

# Fixed point integer-Example for different types

| Binary number | Unsigned | Sign magnitude | Signed 2's complement |
|---------------|----------|----------------|-----------------------|
| 1111          | 15       | -7             | -1                    |
| 1110          | 14       | -6             | -2                    |
| 1000          | 8        | 0              | -8                    |
| 0111          | 7        | 7              | 7                     |

# Fixed point fraction

- Fraction can be represented as follows

$$n = i + f$$

Where n is total no. of bits

Integer Fraction

- Unsigned range

$$[0, 2^i - 2^{-f}]$$

- Signed (2's complement) range

$$[-2^{i-1}, 2^{i-1} - 2^{-f}]$$

# Sign extension Rules

- Rule #1: 2's complement numbers must be the same word-width because of implied zeros

|             |                     |
|-------------|---------------------|
| 0 0 1 0 1 1 | -5                  |
| 0 1 0 0 1 0 | +18                 |
| -----       |                     |
| 0 1 1 1 0 1 | +29! => Still Wrong |

# Sign extension

- Rule #2: Despite a fundamental change to the number's definition, the value of a 2's complement number will never change due to any amount of sign extension—positive or negative

$$1\ 0\ 1\ 1\ -5 = -8 + 2 + 1$$

$$1\ 1\ 0\ 1\ 1\ -5 = -16 + 8 + 2 + 1$$

$$1\ 1\ 1\ 0\ 1\ 1\ -5 = -32 + 16 + 8 + 2 + 1$$

# Sign extension

- Procedure:
  - Calculate the width of the answer word so that it contains all input possibilities
    - It's up to you to make sure the output range is sufficient
  - Extend the inputs' sign bits to the width of the answer
  - Add as usual
  - Ignore bits that ripple to the left of the answer's MSB

$$\begin{array}{r} \mathbf{111011} \quad -5 \\ 010010 \quad +18 \\ \hline x001101 \quad +13 \end{array}$$
